Advanced Homework 3

Due: Wednesday, October 4th, 11:59PM (Hard Deadline)

Submission Instructions

To receive credit for this assignment you will need to stop by someone's office hours, demo your running code, and answer some questions. Make sure to check the office hour schedule as the real due date is at the last office hours before the date listed above. This applies to assignments that need to be gone over with a TA only.

1 Pretty PS1

Open a new terminal and try the following commands in order:

```
echo -e "\\033[44;3;70;38;5;214m"
                                                12 pwd
                                                13 bash --norc
   <hit enter again>
3
   PS1="Hello World -- "
                                                14 echo -e "\\033[44;3;70;38;5;214m"
4
   echo -e "\\033[44;3;70;38;5;214m"
                                                15
                                                   1 s
   pwd
                                                16 pwd
5
6
                                                17 ls --color=auto
  ls
7
                                                18 pwd
  pwd
   echo -e "\\033[44;3;70;38;5;214m"
                                                19 exit
  ls --color=none
                                                20 PS1="\\033[44;3;70;38;5;214mHello Again -- "
                                                21
10
  pwd
11
  reset
```

What happened to your terminal as you ran these commands? Play around with some other forms of PS1 and other colors, see what happens. Why does calling 1s sometimes reset things?

Create a custom PS1 for yourself. Look into some of the options for PS1, you will need to explain why you added the options you did and decided against options you didn't choose.

Extend your PS1 by writing a bash function the changes your prompt in a way that is not built-in to bash. Some examples: Add an asterisk if your are in a git repository with uncommitted changes. Change the color if you are currently in a shared directory (i.e. in a Dropbox folder). Change the color if the current directory will not be saved across a reboot (i.e. if you are you are somewhere in the /tmp directory).

Submission checkoff:

Explain what PS1 does
Explain what you did to customize $PS1$ and \mathbf{why} you chose the customizations that you did
\square Explain how your custom function works.
Explain what the PS2 variable controls. Change PS2 from the default and show an example.
Type set -x. Then type 1s. Explain all of the output.

2 Understanding tab completions

Open a new terminal and try typing the following (note <tab> means press the tab key):

```
1 p<tab><tab>
2 y
3 <ctrl-c>
4 pi<tab><tab>
5 pin<tab><tab>
6 ping<tab><tab>
7 ping <tab><tab>
8 PATH=<enter>
9 p<tab><tab></tab>
```

In addition to finding programs, tab completions can help you to use a program correctly by hinting at what arguments a program accepts, try this:

```
10  # Open a new terminal (or manually set your PATH correctly again)
11  ping <tab><tab>
12  ping -<tab><tab>
13  ping -I<tab><tab>
14  ping -Q<tab><tab>
15  ping -Q 0 <tab><tab></tab></tab>
```

Today, most programs include tab completion support, but this is a remarkably manual process. Check out the contents of the /usr/share/bash-completion/completions/ directory.

Now take a look at /usr/share/bash-completion/completions/ping. There's a lot going on in this example, but try to see if you can understand some of how the completions are working. What do you think the result of ping -T <tab><tab> will be?

(Hint: || in bash means "if the previous thing failed, do the next thing". What's the output of echo \$OSTYPE? Will that equality pass or fail?)

Submission checkoff:

	Why is the list of tab completions different between lines 1 and 9?
П	What is the default tab completion behavior for a program if no custom completion function has been written

3 Testing Made Easy

When working on a project in EECS, you should be writing test cases to make sure your program is functioning properly. Checking your test cases can be tedious, but fortunately for us, scripting can help make it really easy to run your test cases and report which ones are passing and which ones are failing. Here, we will do just that.

Go ahead and download some files from this URL, extract them, and take a look. You should see 3 files. testPass.sh, testFail.sh, and testTimeout.sh. You should not need to modify their contents.

```
> wget https://c4cs.github.io/static/w17/advanced/wk3-advanced-p3-files.tar.gz
> # eXtract Ze Files
> tar xzf wk3-advanced-p3-files.tar.gz
```

Write a few more shell scripts (2 or 3) with the string "test" somewhere in the name. These should run a program of your choice and test the output to make sure the program is passing the test case. The program's output can be as simple as "Hello, World!", but the test case must correctly check the output of the target program and signal whether the target program has passed or failed.

Then, write a shell script which takes all files in the current directory with "test" somewhere in the name, runs each of them, and reports whether the program passed or failed the test case by printing "PASSED", "FAILED". Your script should also stop programs from running for more than 3 seconds and print "TIMEOUT". Your individual test case scripts should not print anything, but the test runner script should.

Submission checkoff:

How does the exit command work? (Hint: How is this similar to return in $C/C++?$)
How can a test case report to our test running script whether the target program passed or failed?
How can you tell if a program is running too long?
Can you demo your code?
